

The 5 Animation Skills

Every install command, plus what to prompt once each one is in. All five are public repos. Nothing here is paid or sponsored.

READ THIS FIRST

Skills are not prompts

You install a skill once and Claude keeps the capability. That is the whole point. You stop re-explaining the same context every session, and your output stops looking like a default template.

Most of these install through npx skills, a third party CLI that works with Claude Code, Cursor, Codex, Copilot and 40 or so other agents. It auto detects whichever agent you have installed. Genjutsu is the exception and installs as a Claude Code plugin.

On Claude Code, installed skills live in `~/.claude/skills/` when they are global, or in `.claude/skills/` inside a project when they are local to it. If you ever want to check what is actually loaded, look there.

THE ORDER

Install Design DNA first

They stack, and the order matters more than people expect:

- Design DNA sets the visual direction, so everything built after it inherits a real palette and type scale instead of defaults.
- GSAP and Motion Design handle how things move.
- Three.js adds depth once the flat version already looks right.
- Genjutsu is the finishing pass, so it goes last by definition.

If you are only going to install one, make it Design DNA. It changes how everything else you build looks, and you see the difference immediately.

SKILL 01 OF 05

Three.js

CloudAI-X/threejs-skills

Nine skill files covering fundamentals, geometry, materials, lighting, shaders, loaders, animation, interaction and postprocessing. This is the one that turns a flat page into something you can move around in.

INSTALL

```
npx skills add CloudAI-X/threejs-skills
```

Its README tells you to clone pinkforest/threejs-playground. That repo returns a 404, so use the command above instead.

THEN PROMPT

Build a full screen Three.js hero for my landing page: a slowly rotating [object] with soft studio lighting and a scroll linked camera dolly. Use the threejs-fundamentals, threejs-lighting and threejs-animation skills. Lazy load the renderer, cap the pixel ratio at 2, and dispose geometries on unmount.

SKILL 02 OF 05

GSAP

greensock/gsap-skills

The official GreenSock skill. Timeline animation, ScrollTrigger, text reveals and React integration. If you have ever wondered why the good sites feel that smooth, this is it.

INSTALL

```
npx skills add https://github.com/greensock/gsap-skills
```

Inside a Claude Code session you can use the plugin marketplace instead: /plugin marketplace add greensock/gsap-skills

THEN PROMPT

Animate this page with GSAP: a staggered character reveal on the h1, a ScrollTrigger pin on the features section, and a slow parallax on the hero image. Put everything on one master timeline so I can retime the whole sequence from a single place, and wrap it in a prefers-reduced-motion guard.

SKILL 03 OF 05

Design DNA

zanwei/design-dna

Point it at a site you like and it extracts the design as machine readable tokens. Color palette, typography, layout, spacing. You stop guessing why something looks expensive.

INSTALL

```
npx skills add zanwei/design-dna
```

To install for one agent only, non interactive and global: `npx skills add zanwei/design-dna -a claude -g -y`

THEN PROMPT

Extract the design DNA of [paste a URL]. Give me the color palette with hex values, the type scale, the spacing rhythm, border radii, shadow style and the layout grid. Output it as design tokens I can paste straight into my Tailwind config, then rebuild my [page name] using only those tokens.

SKILL 04 OF 05

Motion Design

LottieFiles/motion-design-skill

Built by the LottieFiles team. Lottie and SVG animation, keyframes, interactive states, and export straight to JSON or dotLottie.

INSTALL

```
npx skills add LottieFiles/motion-design-skill
```

THEN PROMPT

Design a Lottie ready loading animation for [brand]: a 2 second loop with three states, idle, loading and success. Keep it SVG based and under 30kb. Export the dotLottie plus the raw JSON, then give me the React component that plays the success state when my form submits.

SKILL 05 OF 05

Genjutsu

AThevon/genjutsu

Creative direction and the finishing pass. Fifteen modules across foundations, web, Apple and Android, so it also covers SwiftUI and Compose, not just the web.

INSTALL

```
/plugin marketplace add AThevon/genjutsu
/plugin install genjutsu
```

This one is a plugin, not an npx skill. Both lines are slash commands typed inside a Claude Code session, not in your terminal.

THEN PROMPT

```
/genjutsu:cast make the pricing cards feel physical on hover
```

Use `/genjutsu:cast` to add motion and intention to something you already built, and `/genjutsu:paint` when you want it to take the visual direction further. You can pass the request on the same line as the command.

WHY BOTHER

What actually changes

Without the skills	With them installed
Claude writes Three.js from general memory and gets constructor signatures wrong	Real API references and working patterns for nine areas of the library
You describe the look you want in adjectives every single time	You hand it a URL and it extracts the tokens
Animation comes out as generic CSS transitions	Timelines, ScrollTrigger and Lottie exports you can actually ship
Every session starts from zero context	The capability persists, so you start from where you left off

HONEST NOTES

Before you install all five

- All five repos are public and free. I am not affiliated with any of them and none of this is sponsored.
- A skill is context, not magic. It makes Claude accurate about a library, it does not make taste appear.
- npx skills is a community CLI from vercel-labs, not an Anthropic product. Read what a skill contains before you install it, the same way you would with any dependency.
- Skill repos move. If a command here stops working, the repo README is the source of truth.
- Installing all five at once eats context. Start with one, use it on a real build, then add the next.

Built by @nocodealex. If this was useful, the carousel it came from is worth saving for your next build session.
